Integrated photonic quantum technologies

Jianwei Wang^①, Fabio Sciarrino^②, Anthony Laing^③ and Mark G. Thompson^{③*}

Quantum technologies comprise an emerging class of devices capable of controlling superposition and entanglement of quantum states of light or matter, to realize fundamental performance advantages over ordinary classical machines. The technology of integrated quantum photonics has enabled the generation, processing and detection of quantum states of light at a steadily increasing scale and level of complexity, progressing from few-component circuitry occupying centimetre-scale footprints and operating on two photons, to programmable devices approaching 1,000 components occupying millimetre-scale footprints with integrated generation of multiphoton states. This Review summarizes the advances in integrated photonic quantum technologies and its demonstrated applications, including quantum communications, simulations of quantum chemical and physical systems, sampling algorithms, and linear-optic quantum information processing.

Silica-on-Silicon Waveguide Quantum Circuits

Alberto Politi, Martin J. Cryan, John G. Rarity, Siyuan Yu, Jeremy L. O'Brien*

Quantum technologies based on photons will likely require an integrated optics architecture for improved performance, miniaturization, and scalability. We demonstrate high-fidelity silica-on-silicon integrated optical realizations of key quantum photonic circuits, including two-photon quantum interference with a visibility of $94.8 \pm 0.5\%$; a controlled-NOT gate with an average logical basis fidelity of $94.3 \pm 0.2\%$; and a path-entangled state of two photons with fidelity of $>92\%$. These results show that it is possible to directly "write" sophisticated

sists of nested classical and quantum interferometers (e.g., Fig. 1C). In a standard optical implementation, the photons propagate in air, and the circuit is constructed from mirrors and beam splitters (BSs), or half-reflective mirrors, which split and recombine optical modes, giving rise to both classical and quantum interference. High visibility quantum interference (2δ) demands excellent optical mode overlap at a BS, which requires exact alignment of the modes, whereas high visibility classical interference also requires subwavelength stability of optical path lengths, which often necessitates the design and imple-

Quantum key distribution (QKD) is a quantum communication technology that promises unconditional communication security. High-performance and cost-effective QKD systems are essential for the establishment of quantum communication networks^{1–3}. By integrating all the optical components (except the laser source) on a silicon photonic chip, we have realized a

was further pushed. Very recently, several detection of photons were reported. The of 4.5 kV A^{-1} with 15 Here we report a

Large-scale, highly integrated and low-power-consuming hardware is becoming progressively more important for realizing optical neural networks (ONNs) capable of advanced optical computing. Traditional experimental implementations need N^2 units such as Mach-Zehnder interferometers (MZIs) for an input dimension N to realize typical computing operations (convolutions and matrix multiplication), resulting in limited scalability and consuming excessive power. Here, we propose the integrated diffractive optical network for imple-

Reducing noise in quantum systems is a major challenge towards the application of quantum technologies. Here, we propose and demonstrate a scheme to reduce noise using a quantum autoencoder with rigorous performance guarantees. The quantum autoencoder learns to compresses noisy quantum states into a latent subspace and removes noise via projective measurements. We find various noise models where we can perfectly reconstruct the original state even for high noise levels. We apply the autoencoder to cool thermal states to the ground state and reduce the cost of magic state distillation by several orders of magnitude. Our autoencoder can be implemented using only unitary transformations without ancillas, making it immediately compatible with the state of the art. We experimentally demonstrate our methods to reduce noise in a photonic integrated circuit. Our results can be directly applied to make quantum technologies more robust to noise.

Superdense coding

a**b**

A dual-wavelength pump beam is injected into the photonic chip and separated into 16 paths to generate the weak single-mode squeezed states

**c**

Injected into a 16-mode unitary matrix which is composed of 120 MZIs for realizing the Bell state measurement.

(Bob) High-dimension

The two photons are then injected into the superconducting nanowire single-photon detectors. Each MZI consists of two phase shifters and two multimode interferometers (MMI)

Generation of high dimensional entangled state

A single squeezed state is described as $|\varphi\rangle \approx (|0\rangle_a + p|2\rangle_a)/\sqrt{1+p^2}$ for $p \ll 1$

For the superposition of two adjacent output weak squeezed states labeled as modes a and b , described by

$$|\varphi\rangle = \frac{1}{\sqrt{2}}(|20\rangle_{ab} - |02\rangle_{ab}),$$

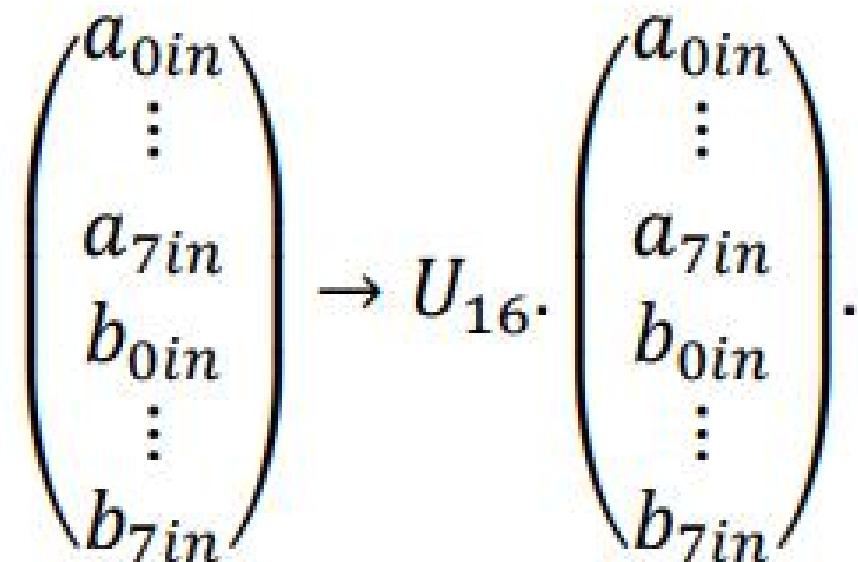

the evolution after passing through a 50:50 beamsplitter is expressed as

Recall squeezed state is:

$$|\varphi\rangle = \exp(\zeta a^\dagger 2 - \zeta^* a^2)|0\rangle$$

$$\begin{aligned} |\varphi\rangle &= (|20\rangle_{ab} - |02\rangle_{ab})/\sqrt{2} \\ &= (a^\dagger 2 - b^\dagger 2)|00\rangle/2 \\ &\xrightarrow{50:50\ BS} [(a^\dagger + b^\dagger)^2/2 - (a^\dagger - b^\dagger)^2/2]|00\rangle/2 \\ &= a^\dagger b^\dagger |00\rangle \\ &= |11\rangle_{ab} \end{aligned}$$

For the 8-dimension Bell states, there exists a set of 64 orthogonal Bell states which can be encoded into 16 spatial modes named as a_0 to a_7 and b_0 to b_7 . But we cannot distinguish all of them with linear optics. So we perform the high-dimension Bell states which can distinguish most of them.

Eleven “Bell” states:

To generate the eleven orthogonal high-dimension Bell states, Alice needs to perform the local operations in the state

$$|\varphi\rangle = \frac{1}{2\sqrt{2}} \left(\begin{array}{c} |a_0 b_0\rangle + |a_1 b_1\rangle + |a_2 b_2\rangle \\ + |a_3 b_3\rangle + |a_4 b_4\rangle + |a_5 b_5\rangle \\ + |a_6 b_6\rangle + |a_7 b_7\rangle \end{array} \right)$$

$$|\psi_0\rangle = (|a_0 b_0\rangle - |a_1 b_1\rangle + |a_2 b_2\rangle - |a_3 b_3\rangle + |a_4 b_4\rangle - |a_5 b_5\rangle + |a_6 b_6\rangle - |a_7 b_7\rangle)/2\sqrt{2}$$
